DESCRIPTION OF PROJECT

The **A-Z Services App** is a full-stack web application designed to provide a seamless platform for customers to connect with professionals offering a wide range of services

TECHNOLOGIES USED

- Flask for application code
- Jinja2 templates + Bootstrap for HTML generation and styling
- SQLite for data storage
- Flask-SQLAlchemy (Database ORM)
- Werkzeug (Security)
- **Matplotlib** (Data Visualization)
- **I/O Operations** (Python io Module)
- **Base64 Encoding** (Python base64 Module)(for rendering images to html pages)

How I Approached the problem statement

I approached the problem statement by first completing the frontend design of my project. In this project I implemented frontend part using bootstrap for responsive design. After completion of frontend part with the help of live sessions I started creating database schema and connecting them using flask and flask-sqlalchemy. My main focus was to implement the functionalities such as managing requests, approving professionals by admin, basically all CURD operations. With the help of bootcamp videos provided by project mentor I have implemented feature of flashing messages which was easier approach for detection of errors and even user friendly .I made sure that user interface was simple yet effective to handle required operations.

DB SCHEMA DESIGN

The database consists of tables such as user, customers , professionals, services, packages, service_requests. These tables are interconnected with foreign keys to maintain integrity. Cascade delete is implemented such that if a record is deleted from primary table(user, service) related records in dependent tables gets deleted automatically.
